The clinical use of computed tomography (CT) and Magnetic Resonance Imaging (MRI) is largely based on an obvious increase in spatial and temporal resolution. However, the spatial resolution of CT is limited by the fact that X-ray attenuation is proportional to the fourth power of the photon energy. Therefore, any reduction in the X-ray energy (i.e., low-energy scans) leads to a significant decrease in the X-ray attenuation, resulting in reduced spatial resolution. In medical applications, a large volume of lung examinations are performed with a low-energy approach. The aim of this study was to quantify the impact of the low-energy approach on image quality using different imaging protocols and variations in the scanning parameters and to discuss possible ways for improving image quality. Image quality, as quantified with a figure-of-merit based on the signal-to-noise ratio (SNR), was simulated for brain and chest examinations using low-energy and conventional protocol. A set of 12 different imaging protocols was evaluated, and the imaging protocol, comprising an energy level, a dose level, an imaging field, and a slice thickness, was termed a "mode". In total, 36 modes were simulated for brain and chest examinations using low-energy and conventional protocol. In addition, the anatomy was removed from one-half of the brain and chest examinations to simulate images with reduced anatomy and from one-half of the chest examinations to simulate images without anatomy. The simulations were performed using a truncated cone sampling projection and a resolution of 320 x 256 pixels. The figures of merit for the low-energy and conventional protocol were larger for the images without anatomy and smaller for the images with anatomy. The smallest figure of merit was found in the "atlas mode" of a 1.5-mm slice thickness and 1% of the EDCT standard dose. The largest figure of merit was obtained in the "thorax mode" of a 0.6-mm slice thickness and 0.5 mSv of radiation dose with CT. The figures of merit were the lowest when the low-energy protocol was selected as the imaging mode. The results indicate that the required dose should be decreased to 0.4-0
